averaged effect

Lg blockage is an anomalous attenuation of waves that propagate in the curst compared to waves propagating below.

Structure of the Pyrenees

in summary

- E-W oriented mountain range
- Jump in Moho depth from up to 50 km (Iberian plate) to about 30
 - 35 km
- Subduction of Iberian lower crust only in the eastern part
- In the western Pyrenees: uplift of lower crustal block into the upper crust (distribution of earthquakes and tomography)

DQ P

Fundamentals of Radiative Transfer Theory

- describes the spatio-temporal distribution of seismic energy
- \Rightarrow model seismogram envelopes
 - neglects wave phenomena (interference)
 - assumes a statistical distribution of heterogeneity
 - may be based on an energy balance consideration

Energy Transfer Equation (acoustic case)

Change of intensity $I(\mathbf{n},\mathbf{r})$ along a path element ds

A decrease due to scattering (g_0) B decrease due to absorption (b)C increase due to sacttering $(g(\mathbf{n}, \mathbf{n}'))$ D increase due to sources

- 4 周 ト 4 戸 ト 4 戸 ト

na (~

$$\frac{\partial}{\partial s}I(\mathbf{n},\mathbf{r}) = -(g_0 + b)I(\mathbf{n},\mathbf{r}) + \int_{4\pi} g(\mathbf{n},\mathbf{n}')I(\mathbf{n}',\mathbf{r})d\Omega_{\mathbf{n}'}$$

Equation of Radiative Transfer Monte-Carlo Technique

イロト イポト イヨト イヨト

DQ P

Elastic case

- 1 P-mode and 2 degenerate S-modes
 - ${\rm \circ}\,$ modes are coupled by conversion scattering coefficients g^{PS} , g^{SP} and g^{SS}
 - S-wave scattering requires the treatment of polarization

イロト イポト イヨト イヨト

DQ P

Monte-Carlo technique to solve the RTE

- discretize the wave and propagate the wave packets independently like particles
- Intensity is modeled as the *number density* of these particles
- Movement of particles is governed by the large scale velocity structure (ray tracing)
- Interaction with medium small scale velocity structure (heterogeneity) by isolated scattering events
- \Leftarrow Probabilities for mode conversion and scattering angles are described by the scattering coefficients $g({\bf n},{\bf n}')$ from the Born-approximation
 - (two S-polarizations are regarded as separate modes)

Characterization of the medium

• Medium has random velocity fluctuations:

$$v(r)=v_0(1+\xi(r))$$
 with $\langle\xi(r)
angle=0$ and $\langle\xi(r)^2
angle=arepsilon^2$

• $\xi(r)$ is characterized by it's spectral density PSD (exponential ACF)

$$PSD(m) = \frac{8\pi\varepsilon^2 a^2}{(1+a^2m^2)^2}$$

with the correlation length a.

• The PSD enters the scattering coefficient g

$$g^{PP}(\Theta) = \frac{l^4}{4\pi} |X^{PP}(\Theta)|^2 PSD\left(\frac{2l}{\gamma_0}\sin\left(\frac{\Theta}{2}\right)\right)$$

Type and amplitude of velocity fluctuation governs the scattering process.

Equation of Radiative Transfer Monte-Carlo Technique

Elastic case – Treatment of the S-Polarisation

- assume linearly polarized waves
- $\Rightarrow \text{ dependence of scattering coefficient on} \\ \text{scattering angle } \Theta \text{ and } \Phi \text{ factorizes} \\ \text{(great advantage for modeling)}$

<ロト <同ト < 三ト < 三ト

Inversion Results Summary

Interpretation

Effect of the continent-continent collision

- eastern Pyrenees: convergent motion led to subduction of Iberian lower crust
- western Pyrenees: no subduction

Convergent and rotational motion led to strong internal deformation with exchange of material between different crustal layers. This heterogeneity causes the increased scattering that is responsible for the Lg-blockage.
